Julia Warnings

Just like Python, Julia lets you do the following:

In [2]:

```
let
    x = [1,2,3]
    @show x
    y = x # NEVER DO THIS, EDITING ONE WILL NOW EDIT BOTH

    y[3] = 100 # this will now modify both y and x
    x[1] = 300 # this will now modify both y and x

    @show x y 1 x.^2
#     @show x
end
```

```
x = [1, 2, 3]
x = [300, 2, 100]
y = [300, 2, 100]
1 = 1
x .^ 2 = [90000, 4, 10000]
```

Out[2]:

```
3-element Vector{Int64}:
 90000
      4
 10000
```

In [3]:

```
# to avoid this, here are two alternatives
let
    x = [1,2,3]
    @show x

    y1 = 1*x           # this is fine
    y2 = deepcopy(x)   # this is also fine

    x[2] = 200 # only edits x
    y1[1] = 400 # only edits y1
    y2[3] = 100 # only edits y2

    @show x
    @show y1
    @show y2
end
```

```
x = [1, 2, 3]
x = [1, 200, 3]
y1 = [400, 2, 3]
y2 = [1, 2, 100]
```

Out[3]:

```
3-element Vector{Int64}:
 1
 2
 100
```

Optional function arguments

We can have optional keyword arguments for functions in Julia, like the following:

In [4]:

```
## optional arguments in functions

# we can have functions with optional arguments after a ; that have default values
let
  function f1(a, b; c=4, d=5)
    @show a,b,c,d
  end

  f1(1,2)           # this means c and d will take on default value
  f1(1,2;c = 100,d = 2) # specify c and d
  f1(1,2;d = -30)    # or we can only specify one of them
end
```

```
(a, b, c, d) = (1, 2, 4, 5)
(a, b, c, d) = (1, 2, 100, 2)
(a, b, c, d) = (1, 2, 4, -30)
```

Out[4]:

(1, 2, 4, -30)

Q1: Integration (20 pts)

In this question we are going to integrate the equations of motion for a double pendulum using multiple explicit and implicit integrators. We will write a generic simulation function for each of the two categories (explicit and implicit), and compare 6 different integrators.

The continuous time dynamics of the cartpole are written as a function:

$$\dot{x} = f(x)$$

In the code you will see `xdot = dynamics(params, x)`.

Part A (10 pts): Explicit Integration

Here we are going to implement the following explicit integrators:

- Forward Euler (explicit)
- Midpoint (explicit)
- RK4 (explicit)

In [5]:

```

# these two functions are given, no TODO's here
function double_pendulum_dynamics(params::NamedTuple, x::Vector)
    # continuous time dynamics for a double pendulum given state x,
    # also known as the "equations of motion".
    # returns the time derivative of the state,  $\dot{x}$  (dx/dt)

    # the state is the following:
     $\theta_1, \theta_1, \theta_2, \theta_2 = x$ 

    # system parameters
    m1, m2, L1, L2, g = params.m1, params.m2, params.L1, params.L2, params.g

    # dynamics
    c = cos( $\theta_1 - \theta_2$ )
    s = sin( $\theta_1 - \theta_2$ )

     $\dot{x} = [$ 
         $\theta_1;$ 
         $(m_2 * g * \sin(\theta_2) * c - m_2 * s * (L_1 * c * \theta_1^2 + L_2 * \theta_2^2) - (m_1 + m_2) * g * \sin(\theta_1)) / (L_1 * (m_1 + m_2 * s^2));$ 
         $\theta_2;$ 
         $((m_1 + m_2) * (L_1 * \theta_1^2 * s - g * \sin(\theta_2) + g * \sin(\theta_1) * c) + m_2 * L_2 * \theta_2^2 * s * c) / (L_2 * (m_1 + m_2 * s^2));$ 
     $]$ 

    return  $\dot{x}$ 
end
function double_pendulum_energy(params::NamedTuple, x::Vector)::Real
    # calculate the total energy (kinetic + potential) of a double pendulum given a state x

    # the state is the following:
     $\theta_1, \theta_1, \theta_2, \theta_2 = x$ 

    # system parameters
    m1, m2, L1, L2, g = params.m1, params.m2, params.L1, params.L2, params.g

    # cartesian positions/velocities of the masses
    r1 = [L1 * sin( $\theta_1$ ), 0, -params.L1 * cos( $\theta_1$ ) + 2]
    r2 = r1 + [params.L2 * sin( $\theta_2$ ), 0, -params.L2 * cos( $\theta_2$ )]
    v1 = [L1 *  $\theta_1$  * cos( $\theta_1$ ), 0, L1 *  $\theta_1$  * sin( $\theta_1$ )]
    v2 = v1 + [L2 *  $\theta_2$  * cos( $\theta_2$ ), 0, L2 *  $\theta_2$  * sin( $\theta_2$ )]

    # energy calculation
    kinetic = 0.5 * (m1 * v1' * v1 + m2 * v2' * v2)
    potential = m1 * g * r1[3] + m2 * g * r2[3]
    return kinetic + potential
end

```

Out[5]:

double_pendulum_energy (generic function with 1 method)

Now we are going to simulate this double pendulum by integrating the equations of motion with the simplest explicit integrator, the Forward Euler method:

$$x_{k+1} = x_k + \Delta t \cdot f(x_k) \quad \text{Forward Euler (explicit)}$$

In [6]:

```

"""
    x_{k+1} = forward_euler(params, dynamics, x_k, dt)

Given  $\dot{x} = \text{dynamics}(\text{params}, x)$ , take in the current state  $x$  and integrate it forward  $\Delta t$ 
using Forward Euler method.
"""
function forward_euler(params::NamedTuple, dynamics::Function, x::Vector, dt::Real)::Vector
    #  $\dot{x} = \text{dynamics}(\text{params}, x)$ 
    # TODO: implement forward euler
    return x + dt * dynamics(params, x)
end

```

Out[6]:

Part B (10 pts): Implicit Integrators

Explicit integrators work by calling a function with x_k and Δt as arguments, and returning x_{k+1} like this:

$$x_{k+1} = f_{\text{explicit}}(x_k, \Delta t)$$

Implicit integrators on the other hand have the following relationship between the state at x_k and x_{k+1} :

$$f_{\text{implicit}}(x_k, x_{k+1}, \Delta t) = 0$$

This means that if we want to get x_{k+1} from x_k , we have to solve for a x_{k+1} that satisfies the above equation. This is a rootfinding problem in x_{k+1} (our unknown), so we just have to use Newton's method.

Here are the three implicit integrators we are looking at, the first being Backward Euler (1st order):

$$f(x_k, x_{k+1}, \Delta t) = x_k + \Delta t \cdot \dot{x}_{k+1} - x_{k+1} = 0 \quad \text{Backward Euler}$$

Implicit Midpoint (2nd order)

$$x_{k+1/2} = \frac{1}{2}(x_k + x_{k+1})$$

$$f(x_k, x_{k+1}, \Delta t) = x_k + \Delta t \cdot \dot{x}_{k+1/2} - x_{k+1} = 0 \quad \text{Implicit Midpoint}$$

Hermite Simpson (3rd order)

$$x_{k+1/2} = \frac{1}{2}(x_k + x_{k+1}) + \frac{\Delta t}{8}(\dot{x}_k - \dot{x}_{k+1})$$

$$f(x_k, x_{k+1}, \Delta t) = x_k + \frac{\Delta t}{6} \cdot (\dot{x}_k + 4\dot{x}_{k+1/2} + \dot{x}_{k+1}) - x_{k+1} = 0 \quad \text{Hermite-Simpson}$$

When you implement these integrators, you will update the functions such that they take in a dynamics function, x_k and x_{k+1} , and return the residuals described above. We are NOT solving these yet, we are simply returning the residuals for each implicit integrator that we want to be 0.

In [11]:

```
# since these are explicit integrators, these function will return the residuals described above
# NOTE: we are NOT solving anything here, simply return the residuals
function backward_euler(params::NamedTuple, dynamics::Function, x1::Vector, x2::Vector, dt::Real)::Vector
    return x1 + dt*dynamics(params, x2) - x2
end
function implicit_midpoint(params::NamedTuple, dynamics::Function, x1::Vector, x2::Vector, dt::Real)::Vector
    x_mid = 0.5*(x1 + x2)
    return x1 + dt*dynamics(params, x_mid) - x2
end
function hermite_simpson(params::NamedTuple, dynamics::Function, x1::Vector, x2::Vector, dt::Real)::Vector
    x_mid = 0.5*(x1 + x2) + (dt/8)*(dynamics(params, x1) - dynamics(params, x2))
    return x1 + (dt/6)*(dynamics(params, x1) + 4*dynamics(params, x_mid) + dynamics(params, x2)) - x2
end
```

Out[11]:

hermite_simpson (generic function with 1 method)

Out[16]:

Test.DefaultTestSet("energy behavior", Any[], 6, false, false)

Another important takeaway from these integrators is that explicit Euler results in unstable behavior (as shown here by the growing energy), and implicit Euler results in artificial damping (losing energy). Implicit midpoint however maintains the correct energy. Even though the solution from implicit midpoint will vary from the initial energy, it does not move secularly one way or the other.
